

## KM414 Setpoint/ Display Panel

The KM414 Setpoint/Display Panel is a low cost/high performance man/machine interface with a broad range of operator input and display capabilities. The panel includes six field points which can be used for either setpoint entry or data display.

The eight-digit numeric LED display is associated with six field points. The user can select which field point to project on the display by use of the SELECT button. The LEDs adjacent to the user-defined field point labels highlight which field point is active. Once selected, the display will either show the related data or project the current setpoint value.

Setpoint adjustment can be performed by **Applications** use of the arrow keys to move the value up or down. Once set, the value is saved into nonvolatile memory. It is permanently stored, whether power remains on or not, until the next time it is changed by the operator.

Each field point can be custom labeled by the user with plastic inserts. The inserts can be custom legended with text and/or graphics, and slipped into a protective pocket behind the faceplate.

The KM414 Setpoint/Display Panel is part of Optimation's **OptiMate**® series. Each 6 Se OptiMate module is designed to connect to a PLC with a single cable connection. OptiMate 400 Series panels can be used individually with a PLC or in a Microprocessor system.

When used with a PLC, operation is transparent to the user. Panel functions tie directly into your PLC ladder logic program. The KM414 takes care of the rest.

## Configuration Options

### **PLC Stand Alone**

OptiMate panels plug directly into most PLCs. A cable connection allows you to interface and control the OptiMate computers or microcontrollers. The modules communicate panel via PLC data registers and ladder logic.

The KM414 Setpoint/Display Panel uses a bank of PLC registers. Complete operator interface is performed with 15 PLC registers for data entry and display. The KM414 the user to directly read setpoint values and write data to continuously accesses these PLC registers and performs display points. operations under ladder logic control on a real-time basis.

ports. This means that a panel attached to the standard port must each serial communications port. control the transfer of information by reading and writing the PLC registers. OptiMate panels will perform this communication for most major PLC protocols. Configuration is the system master. The OptiMate modules are slave devices for particular PLC protocols and interconnect cabling is that respond to commands from the host. In the case of the covered in the following pages.

### Microprocessor-Based Systems

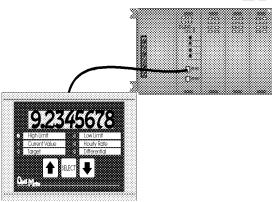

OptiMate 400 Series modules can interface directly to most over RS232 serial communications. All that is required to interface OptiMate modules is an RS232 serial port and the ability to send and receive Hex numbers. The OptiMate Hex communications protocol, detailed in this document, allows

Since the OptiMate 400 Series panels can only PLCs are slave devices on their standard communications communicate on RS232, only 1 panel can be interfaced on

> KM414, these commands are requests for setpoint values and messages that update display points.

## Use with a PLC

### **Memory Mapping**

Memory mapping is a technique that "maps" the memory of an OptiMate panel into the registers of the programmable controller. By knowing where the data of the specific OptiMate panel is mapped, this data can be moved, changed or monitored using ladder logic.

The term PLC register is used for the area of memory within the programmable controller used for data exchange with the KM414. PLC registers

MS	В														LSB
16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1

### **PLC** Register

are sometimes known as data registers or internal registers.

KM41	4 Panel PLC Register Map
PLC Register	Register Function
X	Field point 1 data cell
X+1	Field point 1 data cell 2 (long BCD)
X+2	Field point 2 data cell
X+3	Field point 2 data cell 2 (long BCD)
X+4	Field point 3 data cell
X+5	Field point 3 data cell 2 (long BCD)
X+6	Field point 4 data cell
X+7	Field point 4 data cell 2 (long BCD)
X+8	Field point 5 data cell
X+9	Field point 5 data cell 2 (long BCD)
X+10	Field point 6 data cell
X+11	Field point 6 data cell 2 (long BCD)
X+12	Field point force data cell
X+13	Field point force data cell 2 (long BCD)
X+14	Force control

### Register Definition

The following describes the function of the registers shown in the table.

- Register X Field point 1 data. Either setpoint or display, as configured. Numeric data is either a Binary value or the four least significant digits of the BCD long number in field point 1.
- Register X+1- Field point 1
  data cell 2 (used for long BCD
  numbers only). Either setpoint
  or display, as configured. Numeric value is the four most
  significant BCD digits of data
  for field point 1.
- Register X+2 Field point 2 data.
- Register X+3 Field point 2 data cell 2 (used for long BCD numbers only).
- Register X+4 Field point 3 data.
- Register X+5 Field point 3 data cell 2 (used for long BCD numbers only).
- Register X+6 Field point 4
- Register X+7 Field point 4 data cell 2 (used for long BCD numbers only).
- Register X+8 Field point 5 data.
- Register X+9 Field point 5 data cell 2 (used for long BCD numbers only).
- Register X+10 Field point 6 data.

- Register X+11 Field point 6 data cell 2 (used for long BCD numbers only).
- Register X+12 Field point force data. Value to force setpoint equal to when force operation is initiated by the PLC program.
- Register X+13 Field point force data cell 2 (used for long BCD numbers only). Four most significant digits of BCD long value to force setpoint equal to when force operation is initiated by the PLC program.
- Register X+14 Force control. Controls the forcing of setpoints.
  - > FSP bit When set, the field point force data (X+12 and/or X+13) will be forced into the field points that are set to be forced by setting the bits FP1 - FP6. Once the force is finished, the KM414 will clear X+12, X+13 and X+14.
  - > FP1-FP6 Identifies which setpoints must be forced.

X+14									FSP		FP6	FP5	FP4	FP3	FP2	FP1

### **Force Register Bit Association**

### **Operational Overview**

#### Reading a Setpoint

Setpoint data is continuously and transparently written to the associated PLC register(s). To access and use the setpoint data, simply reference the relevant PLC register(s) (X through X+11) in your PLC program.

#### Writing a Display Point

Writing a display value simply requires writing data into the associated PLC register(s) (X through X+11). The KM414 will automatically retrieve and display the data.

#### Forcing a Setpoint

There are times when it is necessary for the PLC program to initialize or override a setpoint. The capability to do so is provided as the Force Setpoint function.

To force a setpoint to a given value, the value should be placed in register(s) X+12 (and X+13 for BCD long numbers). Next the bit(s) (FP1 - FP6) corresponding to the setpoint(s) to be forced must be set and the FSP bit must also be set. When the KM414 panel has forced the setpoint to the required value, it will clear registers X+12, X+13 and X+14.

Note: If the Force Setpoint option is not selected in the OM-WINEDIT Configuration Software, the setpoints cannot be forced. Also, the registers X+12, X+13 and X+14 will not be used by the KM414 and can be used in your PLC program.

### **Numeric Data Types**

There are two types of data that the KM414 can display. They are BCD long (also known as BCD Double) and Binary.

#### **BCD Long Data**

BCD long (or BCD double) data has a range of 0 - 99999999.

To display a BCD long number, place the least significant four digits of the number into the field point data cell. Next, place the most significant four digits into the field point data cell. 2

To read a setpoint BCD long setpoint value, the KM414 continuously places the least significant four digits into the corresponding field point data cell and the most significant four digits into the corresponding field point data cell 2. Simply reference both registers in your PLC program to use the setpoint value.

If the displayed value or the setpoint value is 92345678, the PLC register will display the following: (shown in BCD/Hex format)

BCD Long Data	PLC Register
Field point data cell	5678
Field point data cell 2	9234

#### **Binary Data**

Binary data has a range of 0 - 65535 (0 - FFFF in HEX format).

To display a Binary number in a display point, simply place the Binary value in the appropriate data cell.

To read a Binary setpoint value, reference the appropriate PLC register in your PLC program.

If the displayed value or the setpoint value is 40500, the PLC register will display the following: (shown in BCD/Hex format)

Binary Data	PLC Register
Field point data cell	9E34
Field point data cell 2	XXXX (Don't care)

Note: When configuring the setpoint ranges, ensure that the High Limit is at least one number greater than the Low Limit or the panel will not work properly. This is true for all data types.

### **Decimal point**

The number of digits displayed after the decimal point is configured in the OM-WINEDIT Configuration Software. The decimal point location is configured separately for each field point.

The decimal point is for displaying purposes only and cannot be changed by or written to a PLC register for use in the program. Once configured, it is fixed and cannot be changed without re-configuring the KM414.

For BCD long numbers, the number of digits that can be displayed after the decimal varies from 0 to 7.

For Binary numbers, the number of digits that can be displayed after the decimal varies from 0 to 7 but the highest number that can be displayed is 65535 (i.e. 0.0065535).

## Examples of Use with a Keyence PLC

### **Register Usage**

The OM-WINEDIT Configuration Editor allows you to configure a module to use a block of registers at a starting value that you define. The memory block has to be in the Data Memory (DM) area of memory. For a Keyence PLC, the recommended memory starting register is address DM0000.

Any address within the DM area of memory is valid for the panel. However, Keyence PLCs use some data memory registers for specific instructions. Also, your program may be using registers in the data memory. Refer to your Keyence User's Manual to ensure that the registers you define for the panel do not conflict with registers that are already in use.

Note: Keyence PLCs do not have a means of easily handling BCD long numbers. If the PLC program can be written to manipulate BCD long numbers, the KM414 can handle them. The KM414 has the capability to display them. It can also have BCD long setpoints which it writes to the appropriate registers.

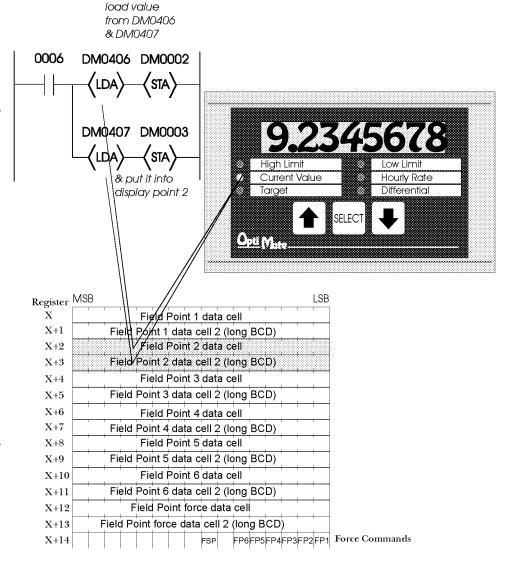

### Setpoint & Display Operations

# Displaying Numeric Data

Displaying numeric data in one of the 6 field points is a very simple process. During the initial configuration, make sure you define the point as a display point, not a setpoint. When this is done, the PLC program must simply put data to be displayed into the register(s) associated with the display data field.

The figure at right illustrates a numeric display application with a Keyence PLC. In this application, the KM414 is configured for a base register address of DM0000 and field point 2 for display, BCD long and 7 digits after the decimal. A BCD long value, held in DM0406 and DM0407 must be displayed in field point 2, DM0002 and DM0003, as long as 0006 is active. The example shows the value transferred from DM0406 and DM0407 to DM0002 and DM0003. It will be displayed as field point 2.

To display a Binary number, simply configure the field point for display, Binary, and the required number of digits after the decimal. Since the Binary data type uses only 1 register, the LDA and STA instructions will only be used on 1 rung.

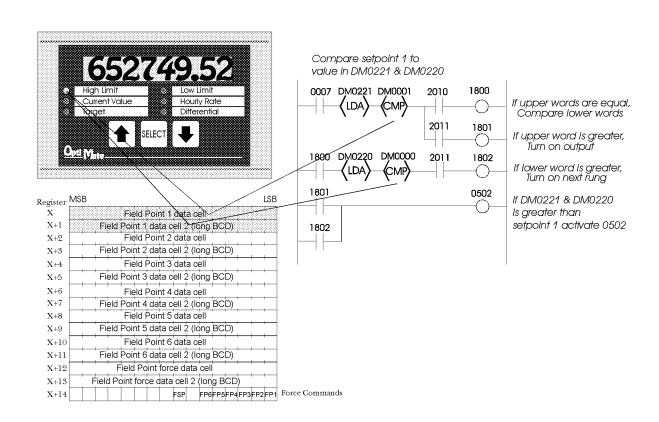

### Reading a Setpoint

The KM414 continuously updates the registers of all setpoints with each setpoint's current value. To read a setpoint, simply access the register(s) that correspond to each setpoint. The data can be copied to another register for manipulation or it can be accessed in its field point register(s).

The following example uses a KM414 at base address DM0000. Field point 1 has been configured as a setpoint, BCD long and 2 digits after the decimal point. In the example program, field point 1 is a High Limit setpoint. Whenever 0007 is active, the program shown checks a value, held in DM0220 and DM0221, against the setpoint value, held in DM0000 and DM0001. If the value exceeds the setpoint, output 0502 will be turned on.

To read a setpoint configured as Binary, simply configure the field point for setpoint, Binary, and the required number of digits after the decimal point. Since the Binary data type uses only 1 register, the LDA and CMP instructions will only be used on 1 rung.

### **Forcing Setpoints**

The KM414 gives you the capability to force a setpoint to a value from the PLC.

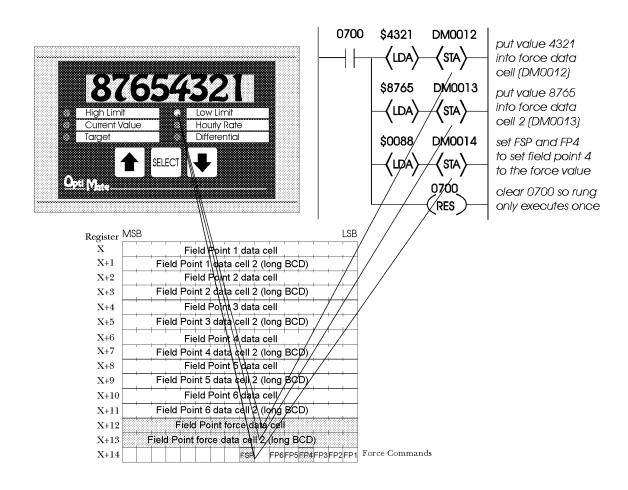

To force a setpoint to a value, the value(s) should be placed in register DM0012 (X+12) (and DM0013 (X+13) if BCD long). Next, the force setpoint bit, FSP, and the bit(s) corresponding to the setpoint(s) to force to this value, must be set in the force control register DM0014 (X+14). When the KM414 completes the force operation, it will clear registers X+12, X+13, and X+14.

The following example shows setpoint 4, a BCD long, being forced to 87654321 when 0700 is active.

Notice that 0700 is used as a set/reset type relay. The force command should be written to the force register once. The KM414 will automatically clear this register when the force is complete. This will normally happen very quickly (less than a second). The fact that the KM414 clears the force control and data registers when the operation is done can be used by the PLC program to verify operation. However, this is generally not necessary.

To force a setpoint that is configured for Binary, only the field point force data cell is used. The field point force data cell 2 is ignored by the panel.

Note: To force setpoints, the Force Enable option must be selected in the OM-WINEDIT software.

## Examples of Use with a Modicon PLC

### Register Usage

The OptiMate Configuration Editor, OM-WINEDIT, allows you to configure the KM414 to use a block of 15 contiguous registers at a starting value that you define. The memory block has to be in the 4x area of memory between 40001 and 40617. For a Modicon PLC, the recommended memory starting register address is 40001.

Any address between 40001 and 40617 area of memory is valid for the panel. However, Modicon PLCs use some data memory registers for specific instructions. Also, your program may be using registers in the 4x memory area. Refer to your Modicon PLC User's Manual to ensure that the registers you define for the panel do not conflict with registers that are already in use.

### **Memory Mapping**

The OptiMate panels communicate in two basic ways with a PLC. They either read data from a register or write data to a register.

The KM414 uses a block of 15 contiguous registers. It *reads* data to display data and to force setpoints. It *writes* data to the setpoint registers to indicate the value of the setpoints.

The first twelve PLC registers (X-X+13) in the block used by the KM414 panel are used for numeric information. As such, they are ideally suited for the 4x memory registers (40001-40617). Since individual bits are used to indicate control and status, register X+14 is better suited for the 0x relay register range of memory. However, the KM414 only communicates with the 4x memory area. The solution to this minor conflict is to define the base register address in 4x area of memory and place a rung in your PLC program to copy from 0x relay registers to register X+14.

Note: Modicon's bit-numbering convention is backwards from the standard (i.e. the least significant register bit is bit 16, while the most significant is bit 1). By carefully documenting bit association, you can avoid confusion.

The examples on the following pages use a KM414 connected to a Modicon PLC. The KM414 is configured for a base address of 40001. The program rung on the right should be placed in the program only if you intend to use the Setpoint Force Option. It copies a relay block starting with 00033 to the Force Control register (X+14).

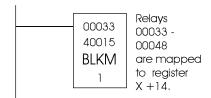

The data registers (X-X+14) depend on the base register address that you define. In this case, the base register address is 40001. Any valid internal relays may be used in the memory map. (If you do not use the relays shown, adjust each to correspond to the relays that you define.)

With the rung shown placed into the PLC program, the force control bits will be relays. The register association is shown in the figure below.

The table below shows the relay correlation for a KM414 when the data memory register X+14 is mapped from the 0x relays beginning with 00033 (as shown in the program rung below).

Force Command
Register (X+14)
00048 (FP1)
00047 (FP2)
00046 (FP3)
00045 (FP4)
00044 (FP5)
00043 (FP6)
00042
00041 (FSP)
00040
00039
00038
00037
00036
00035
00034
00033

Note: Modicon PLCs do not have a means of easily handling BCD long numbers. If the PLC program can be written to manipulate BCD long numbers, the KM414 can handle them. The KM414 has the capability to display them. It can also have BCD long setpoints which it writes to the appropriate registers.

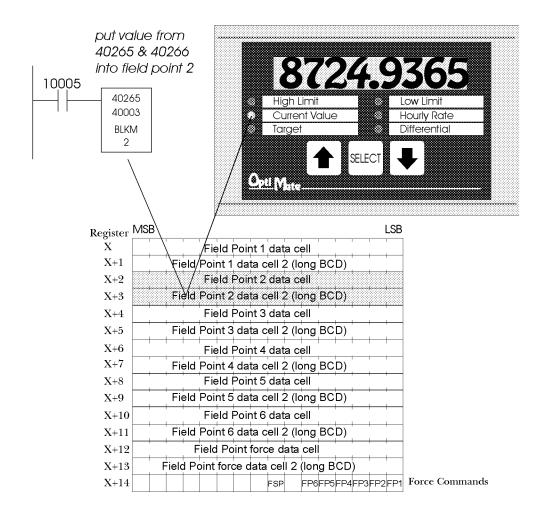

### **Setpoint & Display Operations**

### **Displaying Numeric Data**

Displaying numeric data in one of the 6 field points is a very simple process. During the initial configuration, make sure you define the point as a display point, not a setpoint. When this is done, the PLC program must simply put data to be displayed into the register(s) associated with the display data field.

The figure on the right illustrates a numeric display application with a Modicon PLC. In this application, the KM414 is configured for a base address of 40001. Field point 2 is configured for display, BCD long data and 4 digits after the decimal. A value, held in 40003 and 40004 will be displayed in field point 2 as long as 10005 is active. The example shows the value transferred from 40265 and 40266 to 40003 and 40004. It will be displayed as field point 2.

To display a Binary number, simply configure the field point for display, Binary, and the required number of digits after the decimal point. Only use 1 move instruction to move the data into the field point data cell since the Binary data type uses only 1 register.

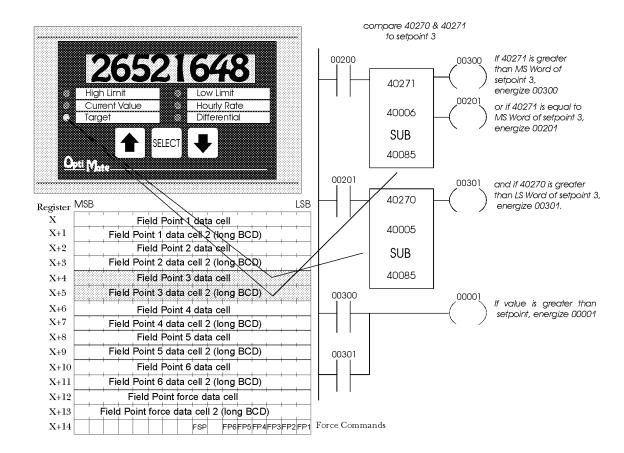

### Reading a Setpoint

The KM414 continuously updates the registers of all setpoints with each setpoints current value. To read a setpoint, simply access the register(s) that corresponds to each setpoint. The data can be copied to another register for manipulation or it can be accessed in its field point register(s).

The following example uses a KM414 at base register address 40001. Field point 3 has been configured as a setpoint, BCD long and 0 digits after the decimal point. In the example program, field point 3 is a Target value setpoint. The program shown below checks a value, held in 40270 and 40271 against the setpoint. If the value exceeds the setpoint, output 00001 will be turned on.

The greater-than comparison of a BCD long number is done by comparing the 4 most significant digits of the setpoint (40006) with the 4 most significant digits of the value that the setpoint is to be compared to (40271). If the comparison value is greater (40271 > 40006), then the entire 8 digit value is greater. Else if the 4 most significant digits of both values are equal (40271 = 40006) and the 4 least significant digits of the comparison value are greater than the 4 least significant digits of the setpoint (40270 > 40005), then the entire 8 digit number is greater. If none of this is true, then the value in 40270 and 40271 is less than the setpoint and 00001 will not be energized.

To read a setpoint that has been configured as Binary, simply configure the field point as a setpoint, Binary, and the required number of digits after the decimal point. Only use 1 comparison statement (SUB) to compare the data since the Binary data type uses only 1 register.

### **Forcing Setpoints**

The KM414 gives you the capability to force a setpoint to a value from the PLC.

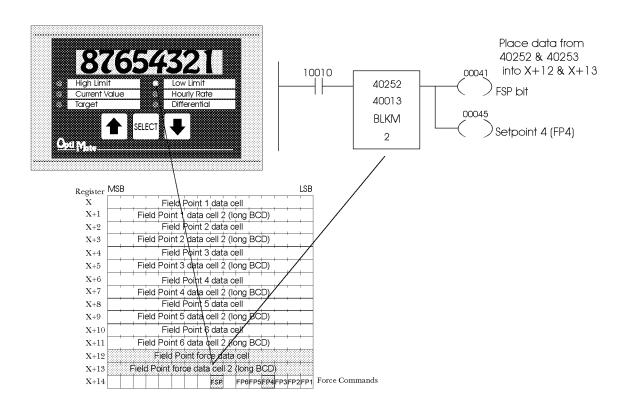

To force a setpoint to a value, the value should be placed in register X+12 (and X+13 if BCD long). Next, the FSP bit, and the bit(s) corresponding to the setpoint(s) to force to this value must be set in the force control register (X+14). When the KM414 completes the force operation, it will clear the force control and data registers.

The following example shows setpoint 4 being forced to 87654321 when 10010 is active. The force value, 87654321, comes from registers 40252 & 40253.

The force command should be written to the force register once. The KM414 will automatically clear this register when the force is complete. This will normally happen very quickly (less than a second). The fact that the KM414 clears the force control register when the operation is done can be used by the PLC program to verify operation. However, this is generally not necessary.

To force a setpoint that is configured for Binary, only the field point force data cell is used. The field point force data cell 2 is ignored by the panel.

Note: To force setpoints, the Force Enable option must be selected in the OM-WINEDIT software.

## Use in a Microprocessor-Based System

OptiMate modules can interface a microprocessor-based controller over a serial link. For the 400 Series line of OptiMate modules, this link is only RS232.

The microprocessor acts as the master. It can write data to the module or read data from the module.

The KM414 uses the OptiMate Hex protocol for fast and easy communications. The OptiMate Hex protocol is defined on the following page.

#### **Module Address**

In a microprocessor-based system, each module must have its own unique address. You define this address (between 0 and 30) during configuration. For the OptiMate 400 Series, the module address is normally 0. The module will respond to the host only if it is properly addressed.

# Communications Protocol

To use an OptiMate module as a slave device in a microprocessor-based system, the module must be configured for the OptiMate Hex protocol. The other options that must be set are module address, baud rate, parity and number of stop bits. If parity is set to even or odd, only one stop bit is allowed. Once selected, it must be downloaded to the module.

# Computer-Based Operation

The KM414 protocol for computer based operation is the OptiMate Hex protocol.

All of the basic functionality described for PLC operation is also available to computer or microprocessor-based applications.

The details of messages involved are covered in the protocol documentation on the following page.

#### Reading a Setpoint

Under computer-based operation, each of the KM414's field points can either be configured for setpoint operation or display. If a field point(s) is/are configured for a setpoint, the value of each field point can be read individually. The "Read Setpoint Data" message (0xA8), detailed on the next page, is transmitted to the panel in hex format. The panel will respond with that particular field points setpoint data in the hex format.

#### Writing a Display Point

If a field point or multiple field points are configured for data display, the data can be sent to each field point individually using the "Write Display Point" message (0xA9). The message including the data is sent in the hex format.

#### Forcing a Setpoint

In some instances, it may be necessary to "force" a setpoint to a particular value to override its current value. That can be done by sending the "Force Setpoint" message (0xAA). The message and data should be sent in the hex format.

### KM414 OptiMate Hex Protocol

## Set Up and Interconnect

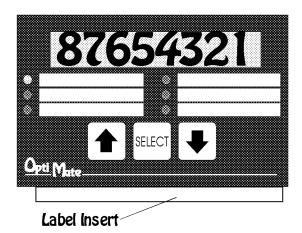

### **Legending the Field Points**

Legending the KM414 module is a relatively simple process that basically involves sliding a legend transparency into a pocket in the panel overlay. Use the following procedure.

- Remove the bezel from the module. The bezel snaps to the module box along the top and bottom edges. Pull the bezel out and over the snaps to remove.
- Create legend transparencies.
   There are a number of available options for doing so. Patterns are provided on the next to last sheet of this document.
  - > Use the built in label-making capability of the OM-WINEDIT software to create labels. Either print on the transparency directly or print on paper and photocopy onto the transparency. The figure below is a screen from OM-WINEDIT which illustrates the process.
  - > Use a computer graphics program and a laser printer to create the transparency directly. Alternately print on paper and photocopy to a transparency.

- > Use press-on letters onto a transparency sheet.
- > Use a typewriter or lettering machine to letter onto paper, then photocopy.
- Cut along outline. Slide into overlay pocket. The legend slides in from the bottom.
- Re-attach bezel. Push bezel onto box until it snaps together. Ensure that the bezel covers all the housing snaps before installing the panel.

### **Connection to the System**

OptiMate modules are designed for communications connection to system devices. The module can be connected to a computer or PLC over the serial port (RS232).

## Connection to a Computer for Configuration

Connection of a 400 Series OptiMate module to a computer for configuration can be accomplished over an RS232 link. RS232 is limited to one OptiMate module to a computer serial port. See the figure below for 400 Series OptiMate Module pinouts.

Refer to manufacturer's documentation for computer serial link connector pinouts.

	ptimate Module on Mode Pinouts

	2 CFG Mode

Configuration cables are available for connection to IBM PC-AT compatible ports.

## Run Mode Connection to a Computer or PLC

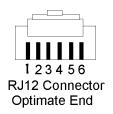

Connection of a 400 Series OptiMate module to a computer or PLC can be accomplished over an RS232 link. RS232 is limited to one OptiMate module to one computer serial port. Since PLCs are slave devices, the RS232 link for a PLC is limited to one OptiMate module. See the figure below for 400 Series OptiMate Module pinouts.

Refer to manufacturer's documentation for PLC or computer serial link connector pinouts.

***************************************	ptimate Module
KUN MC	de Pinouts
	Optimate Module
Host Computer/PLC	RJ12 Phone Jack (6P6C)
TX	3 RS232 RX
RX	4 RS232 TX
Sig Gnd	1 Sig Gnd
	6 Sig Gnd
5VDC	5 5VDC

Standard cables are available for connection to several different PLCs as well as to IBM PC-AT compatible ports.

The figure below shows the RJ12 connector pinout for connection to an OptiMate 400 series module.

#### **Power**

The KM414 Setpoint/Display Panel will operate only on a DC voltage of 5VDC. Steady state current is listed on the specification page.

The KM414 panel can draw power from its communications cable if the host device has a 5VDC connection on its comm port.

The KM414 panel can be powered from a 5VDC adapter for panel configuration or connection to PLCs or microprocessor based devices that do not have a 5VDC connection in their communication ports. A description of the DC power connector is listed on the specification page.

Note: Only use an Optimation approved 5VDC power supply or equivalent that contains a center negative DC power jack.

There is a very brief (0.1 - 1 millisecond) power on surge up to 0.35 amps. This is typical of nearly any type of electronic equipment and is due to the initial charging of power capacitors. This surge is not normally a problem for a commercial power supply.

## **Configuration**

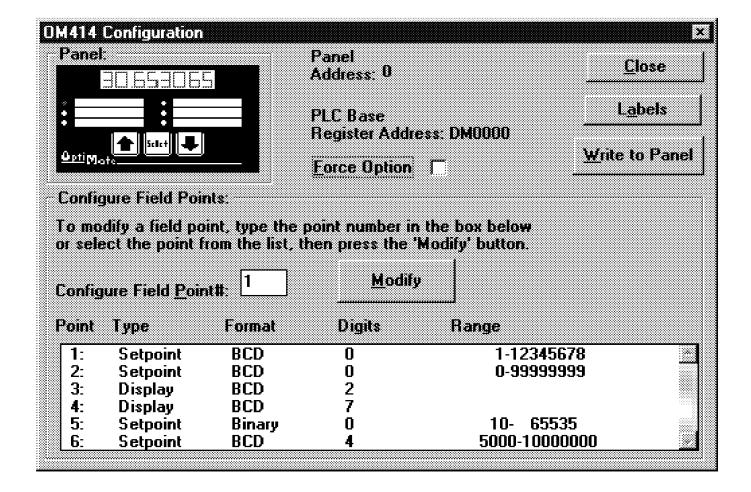

Configuration of the KM414 Setpoint/Display Panel is performed via an IBM PC compatible computer. The OM-WINEDIT configuration software allows you to select panel type, panel application and PLC protocol definition.

If the KM414 is to be operated with a PLC, the configuration selection must be made to select the proper PLC protocol information.

Specific configuration of the KM414 begins with defining the block of PLC registers to be used. Next, each of the field points must be configured for setpoint or display. Additional options exist for setpoint range limits and force enable/disable.

Note: When configuring a KM414, always remember to use the programming cable that connects the KM414 to an IBM PC compatible computer's serial communications port. Also, always insert the programming cable into the panel to place it into configuration mode.

When you are finished downloading the configuration, wait at least 5 seconds before removing the programming cable. This will return the panel to PLC run mode.

### Configuration using a Keyence PLC

The KM414 requires that certain parameters be set in order for it to communicate with a Keyence PLC. The parameters are PLC type, protocol, baud rate, parity, stop bits and base register address. If you are using the KV10, KV16, KV24, KV40 or the KV80

PLCs the KM414 should always be set to the following:

KM414 Communication KV10, KV16, KV24, KV24, KV4	
Baud rate	9600
Parity	even
Stop Bits	1
Data Bits	8

Communications with a KV300 CPU can be accomplished by two means:

- (1) direct connection to the communications port on the CPU
- (2) connecting the panel to a KV-L2 Serial Interface Module

Note: If a KV-L2 Serial Interface Module is connected in the PLC system, you must use it to connect to the KM414. If you try to connect the panel to the KV300 CPU's communications port, the panel will not communicate because the CPU will not recognize the protocol.

#### Direct Connection to the CPU

If you are connected to the KV300 through the CPU communications port, configure the KM414 with the parameters shown in the table above.

The KM414 uses the KV mode protocol to communicate with the PLC, therefore, the port that the panel is communicating with should be set for KV mode also.

#### Communications through the KV-L2

If you are using a KV-L2, the following dip switch parameters apply:

OFF	OFF	OFF	OFF
A1	A2	A3	A3
Pø	rt 1	₽o	rt 2

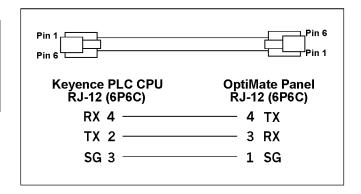

The dip switch settings shown above are dependent on the on the port that the KM414 is connected to. If the panel is connected to Port 1, then switches A1 and A2 should be OFF. If you have another device on Port 2, then the switches for Port 2 should be set to the proper protocol for that device.

The KM414 uses the KV Mode protocol to communicate with Keyence PLCs. Regardless of the "B" dip switch settings, the port that the panel is connected to will automatically default to the communication parameters shown in the table above.

Note: If using Port 2, ensure that the port switch is set for RS232.

Refer to the chapter on the KV-L2 Serial Interface Module in the Keyence User's Manual for more details.

The figure below shows the pinnouts to connect a KM414 to a Keyence PLC CPU. This cable is available from Optimation.

The figure below shows the pinouts to connect a KM414 to a KV-L2 Serial Interface Module. The pinouts shown are for RS232.

KV-L2 to OptiMate	400 Series Panels
KV-L2 Port 1 DB25	OptiMate RJ-12
RX 3	4 TX
TX 2	3 RX
SG 7 ———	1 SG
RS 4 —	
CS 5 —	I
KV-L2 Port 2 DB25	OptiMate RJ-12
RD —	4 TX
SD	3 RX
sg —	1 SG

### **Configuration Selections**

OptiMate modules can be configured for a specific application by using the OptiMate Configuration Editor (OM-WINEDIT). The Configuration Editor runs on any IBM PC compatible computer. It allows the user to select the exact functionality to meet application requirements.

For the KM414 module, the following are important configuration parameters.

#### **Microprocessor Based Systems**

Decision	Selection
Single/Multi Module	Choose Single module even if the system will contain several modules. The Multi module selection applies only to systems using a communications master. In computer-based systems, each module is configured independently.
Configuration starting point	First-time configuration, start with defaults for module. Subsequent configurations can utilize disk files you create.
PLC Type	Select OptiMate Hex
Address	Each module must have a unique address. Normally 0 for the KM414.
Protocol	Select appropriate baud rate, 8 data bits, #stop bits & parity. Note that if even or odd parity selected, only 1 stop bit is available.
Field Points	Define as setpoints or display points as required. Define number format (binary or BCD) and # digits after decimal. For setpoints, define limits.
Force option	If you intend to force setpoint values, enable the force option.

#### Single Panel PLC-Based Systems

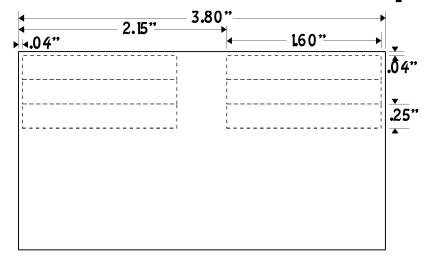

Decision	Selection
Single/ Multi Module	Choose single module configuration
Configuration starting point	First-time configuration start with defaults for module. Subsequent configurations can utilize disk files you create
PLC Type	Select appropriate PLC type
Protocol	Select appropriate baud rate, # data bits, # stop bits & parity. Note that if 8 data bits and even or odd parity selected, only 1 stop bit is available
Field Points	Define as setpoints or display points as required. Define number format in PLC (binary or BCD) and # digits after decimal. For setpoints, define limits.
Force option	If you intend to force setpoint values, enable the force option.

## Multi-Panel PLC Applications (Uses Communications Master)

Not applicable with the 400 Series Modules.

Note: Configuration must be downloaded from an IBM PC compatible computer to each module. This is done over the serial link. Always insert the programming cable into the panel to place it into configuration mode. When you are finished downloading the configuration, wait 5 seconds before removing the programming cable. This will return the panel to PLC run mode. Then insert the proper cable into the panel and the PLC for the panel to operate with the selected host. Communication cables are available from Optimation.

## Field Point Label Insert Template

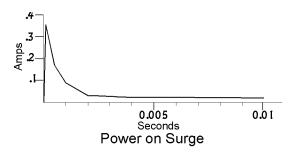

## **Specifications**

#### **Physical**

- Recessed Mount Housing: 6.00"L x 3.50"H x 1.25"D
- Cutout size: 3.20"H x 5.10"L
- Panel Fasteners:Four, 6x32 threaded studs, shown at right (on ends, symmetrical about center line)
- Weight: 8 ounces
- Colors: Dark gray housing with dark gray panel. Keypad keys; white with gray letters.
- Numeric LED height: 0.35 inch
- Pushbutton life: 1,000,000 switch cycles

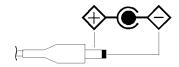

- Power: 5VDC @ 0.85Watts 170 mA @ 5VDC
- Power On Surge (see figure below) 0.35A for 1 millisecond max

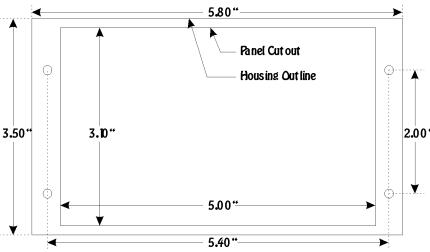

#### Power connector :

DC power plug, center negative (see figure below) DC power plug is necessary for panel configuration and for connection to PLCs that do not have a 5VDC connection in their communication ports.

Always use an Optimation approved 5VDC power supply with a center negative plug.

Panel Mounting Dimensions

#### Communications

- RS232
- 4800 to 19200 baud
- Compatible with major PLC protocols
- Microprocessor compatible OptiMate Hex protocol
- 6 pin RJ12 phone jack type connector

#### **Communications Failure Operation**

Should the panel (when not selected for configuration) ever fail to communicate successfully for a period of 12 seconds, the LEDs on the panel front will flash rapidly.

#### **Environmental**

• Enclosure - NEMA 4 (when properly installed)

• Temperature - 0 to 50 C

• Humidity - 95% Non-condensing
